Tree Implementation

Tiziana Ligorio

tligorio@hunter.cuny.edu

Today's Plan

BST Implementation

Announcements and Syllabus Check

```
#ifndef BST H
#define BST H
#include <memory>
template<class ItemType>
class BST
public:
    BST(); // constructor
    BST(const BST<ItemType>& tree); // copy constructor
    ~ BST(); // destructor
    bool isEmpty() const;
    size t getHeight() const;
    size t getNumberOfNodes() const;
    void add(const ItemType& new item);
    void remove(const ItemType& new item);
    ItemType find(const ItemType& item) const;
    void clear();
    void preorderTraverse(void (*visit)(ItemType&))const;
    void inorderTraverse(void (*visit)(ItemType&))const;
    void postorderTraverse(void (*visit)(ItemType&))const;
    BST& operator= (const BST<ItemType>& rhs);
private:
    std::shared ptr<BinaryNode<ItemType>> root ptr ;
}; // end BST
#include "BST.cpp"
#endif // BST H
```

We are actually going to change this a bit

Let's try something new for fun and use shared_ptr:
A bit of extra syntax at declaration but then you use them as regular pointers with less cleaning up

BinaryNode

```
#ifndef BinaryNode H
                                 For shared ptr
#define BinaryNode_H_
#include <memory> _
template<class ItemType>
class BinaryNode
public:
  BinaryNode();
  BinaryNode(const ItemType& an item);
  void setItem(const ItemType& an item);
  ItemType getItem() const;
  bool isLeaf() const;
   auto getLeftChildPtr() const;
   auto getRightChildPtr() const;
  void setLeftChildPtr(std::shared ptr<BinaryNode<ItemType>> left ptr);
  void setRightChildPtr(std::shared ptr<BinaryNode<ItemType>> right ptr);
private:
  ItemType item ; // Data portion
   std::shared ptr<BinaryNode<ItemType>> left; // Pointer to left child
   std::shared ptr<BinaryNode<ItemType>> right ; // Pointer to right child
}; // end BST
#include "BinaryNode.cpp"
#endif // BinaryNode H
```

Exam Drill

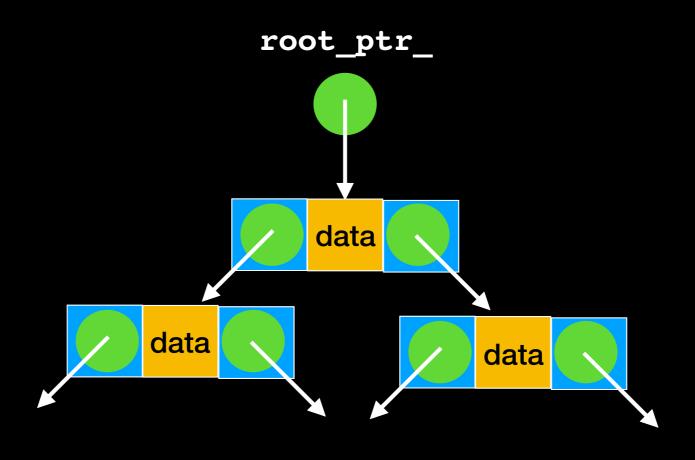

Implement:

```
BinaryNode(const ItemType& an_item);
bool isLeaf() const;

void setLeftChildPtr(std::shared_ptr<BinaryNode<ItemType>> left_ptr);
```

```
template<class ItemType>
BinaryNode<ItemType>::BinaryNode(const ItemType& an_item)
      : item_(an_item), left_(nullptr), right_(nullptr)
{ } // end constructor
template<class ItemType>
bool BinaryNode<ItemType>::isLeaf() const
  return ((left_ == nullptr) && (right_ == nullptr));
} // end isLeaf
template<class ItemType>
void BinaryNode<ItemType>::setLeftChildPtr(std::shared_ptr<BinaryNode<ItemType>> left_ptr)
  left_ = left_ptr;
   // end setLeftChildPtr
```

BST

```
#ifndef BST H
#define BST H
#include <memory>
template<class ItemType>
class BST
public:
    BST(); // constructor
    BST(const BST<ItemType>& tree); // copy constructor
    ~ BST(); // destructor
    bool isEmpty() const;
    size t getHeight() const;
    size t getNumberOfNodes() const;
    void add(const ItemType& new item);
    void remove(const ItemType& new item);
    ItemType find(const ItemType& item) const;
    void clear();
    void preorderTraverse(void (*visit)(ItemType&))const;
    void inorderTraverse(void (*visit)(ItemType&))const;
    void postorderTraverse(void (*visit)(ItemType&))const;
    BST& operator= (const BST<ItemType>& rhs);
private:
    std::shared ptr<BinaryNode<ItemType>> root ptr ;
}; // end BST
#include "BST.cpp"
#endif // BST H
```

We want our interface to be generic and not tied to implementation. Many of these will therefore use helper functions, which should be private (or protected if you envision inheritance). I do not include them here in the interface for lack of space.

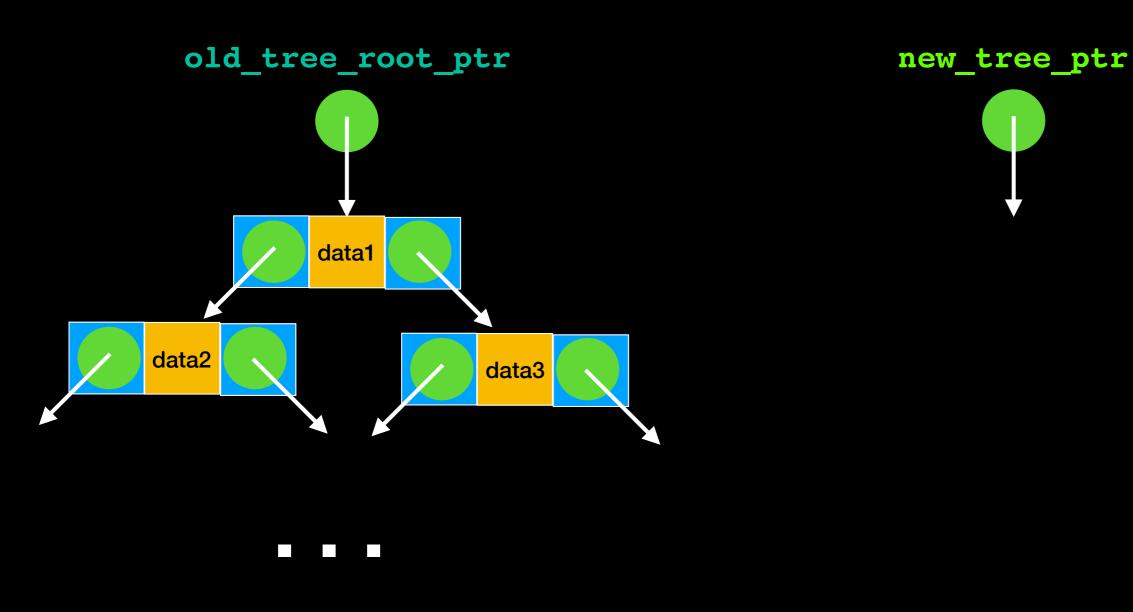

We are actually going to change this a bit

Copy Constructor

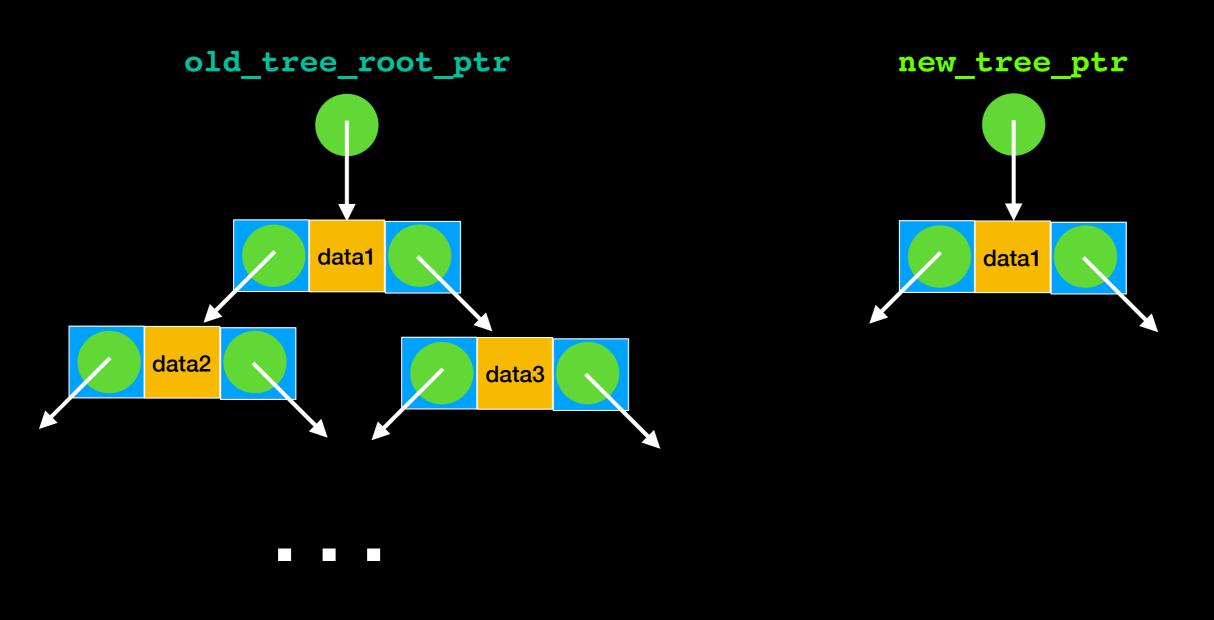

```
template<class ItemType>
BST<ItemType>::BST(const BST<ItemType>& tree)
{
   root_ptr_ = copyTree(tree.root_ptr_); // Call helper function
} // end copy constructor
```

I can use the . operator to access a private member variable because it is s within the class definition.

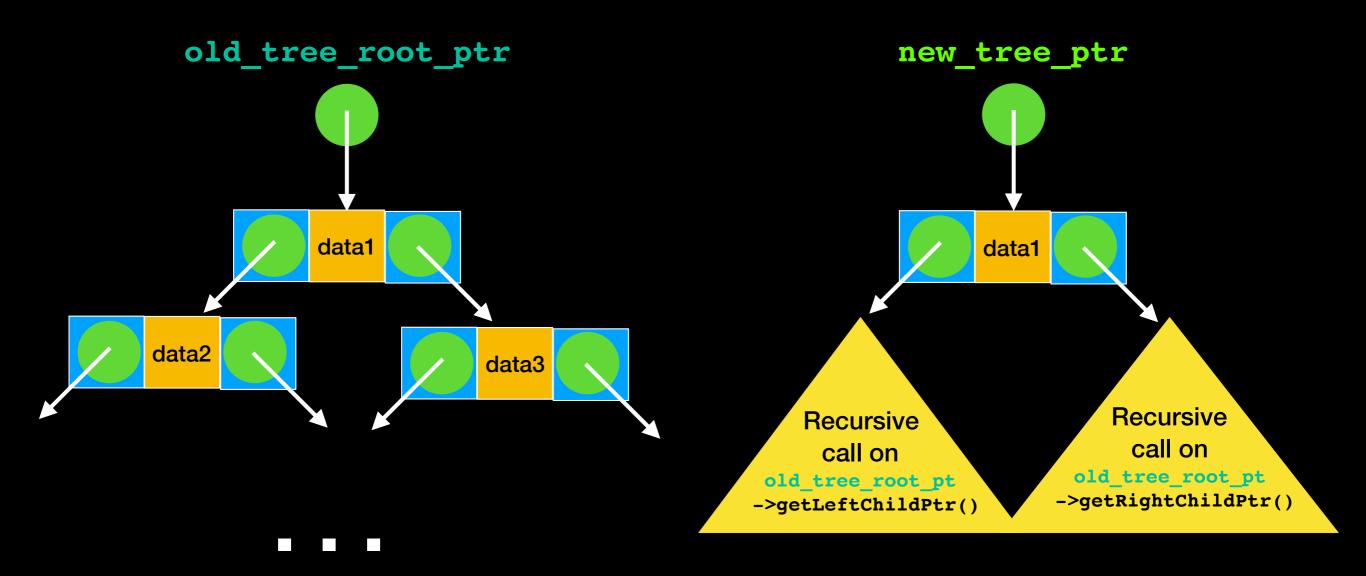

copyTree(old_tree_root_ptr)

copyTree(old_tree_root_ptr)

copyTree(old_tree_root_ptr)

Returning
shared_ptr,
cleaner to use
auto return type:
-std=c++14

return new tree ptr;

// end copyTree

Copy Constructor Helper Function

```
template<class ItemType>
auto BST<ItemType>::copyTree(const std::shared ptr<BinaryNode<ItemType>>
old tree root ptr) const
                                                               Recall: this is the syntax
   std::shared ptr<BinaryNode<ItemType>> new tree ptr;
                                                                for allocating a "new"
                                                               object with shared ptr
      Copy tree nodes during a preorder traversal
                                                                    pointing to it
      (old tree root ptr != nullptr)
      // Copy node
      new tree ptr = std::make shared<BinaryNode<ItemType>>(old tree root ptr
                                                   ->getItem(), nullptr, nullptr);
     new tree ptr->setLeftChildPtr(copyTree(old tree root ptr->getLeftChildPtr()));
      new tree ptr->setRightChildPtr(copyTree(old tree root ptr
                                                             ->getRightChildPtr()));
     // end if
```

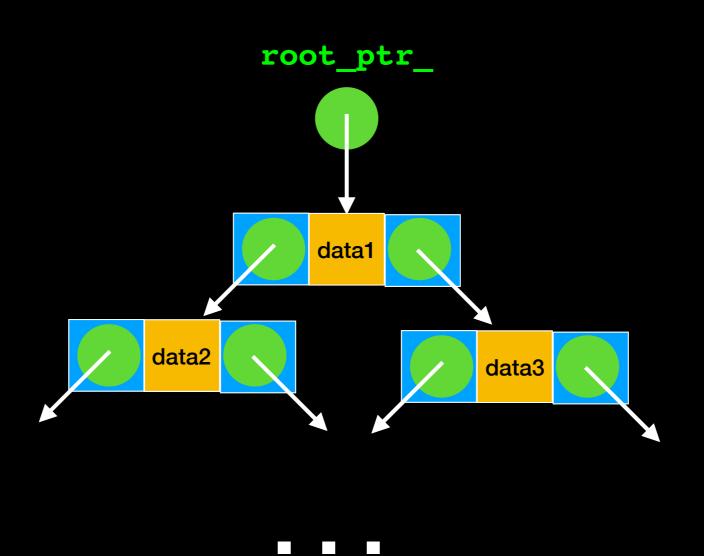

Recursive Calls:

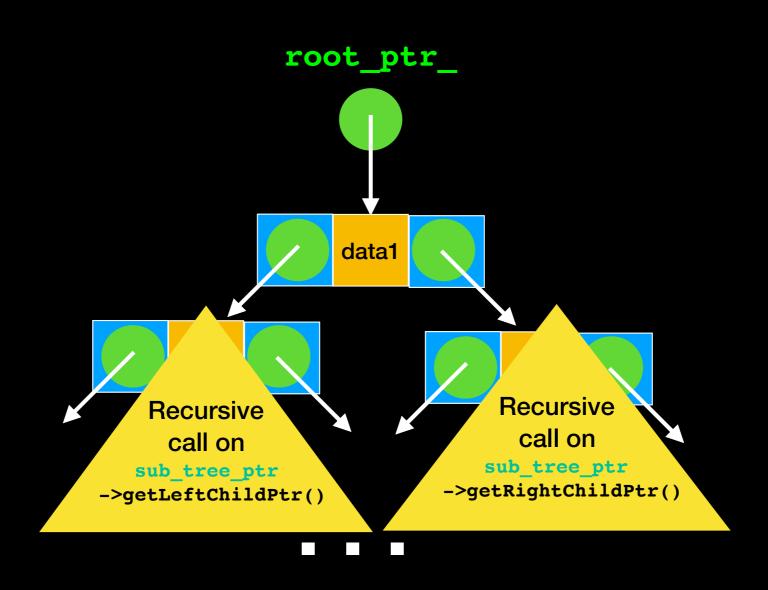

Don't want to tie interface to recursive implementation:
Use helper function

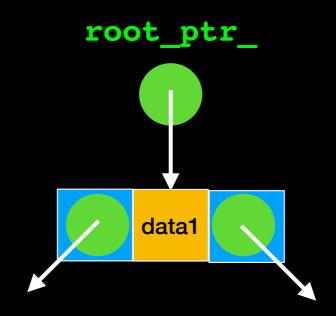

Preorder Traversal Scheme: copy each node as soon as it is visited to make exact copy

Destructor

```
template < class ItemType >
BST < ItemType > :: ~BST()
{
    destroyTree(root_ptr_); // Call helper function
} // end destructor
```

root_ptr_.reset()

root_ptr_

Destructor Helper Function

```
template < class ItemType >
void BST < ItemType > ::destroyTree(std::shared_ptr < BinaryNode < ItemType >> sub_tree_ptr)
{
    if (sub_tree_ptr != nullptr)
    {
        destroyTree(sub_tree_ptr->getLeftChildPtr());
        destroyTree(sub_tree_ptr->getRightChildPtr());
        sub_tree_ptr.reset(); // same as sub_tree_ptr = nullptr for smart pointers
    } // end if
} // end destroyTree
```

Notice: all we have to do is set the shared_ptr to nullptr with reset() and it will take care of deleting the node.

PostOrder Traversal Scheme:
Delete node only after deleting
both of its subtrees

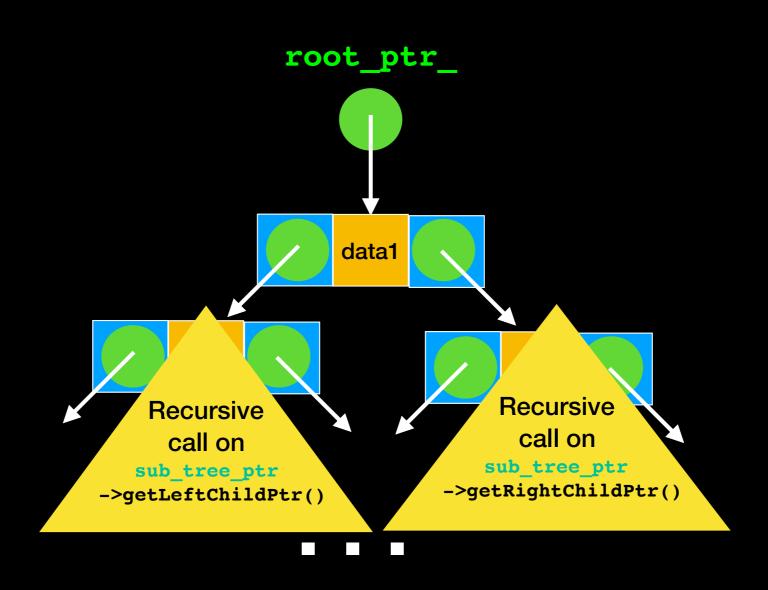

clear

```
template < class ItemType >
void BST < ItemType > :: clear()
{
    destroyTree(root_ptr_); // Call helper method
    root_ptr_.reset();
} // end clear
```

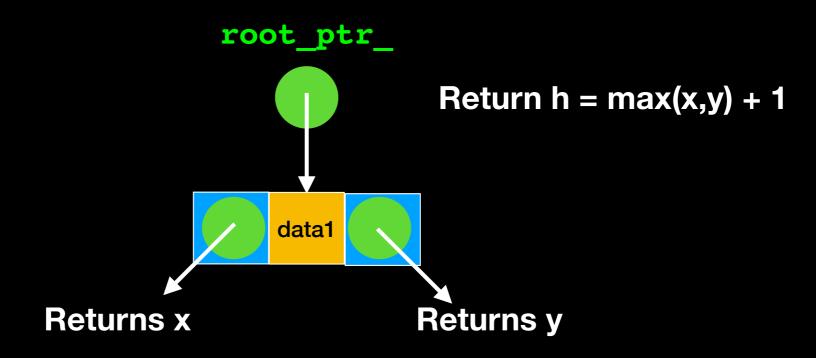

getHeight

```
template < class ItemType >
int BST < ItemType > :: getHeight() const
{
    return getHeightHelper(root_ptr_);
}    // end getHeight
```

getHeightHelper(sub_tree_ptr)

getHeightHelper(sub_tree_ptr)

getHeightHelper(sub_tree_ptr)

Similarly: implement these at home!!!

```
int BinaryNodeTree<ItemType>::getNumberOfNodes() const
{    //try it at home!!!!}
int BinaryNodeTree<ItemType>::getNumberOfNodesHelper(std::shared_ptr
<BinaryNode<ItemType>> sub_tree_ptr) {//try it at home!!!!}
```

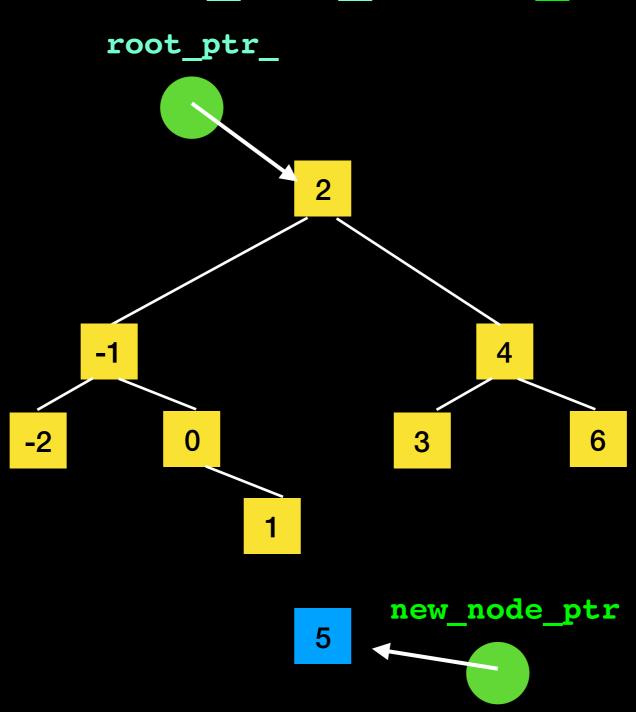

add and remove

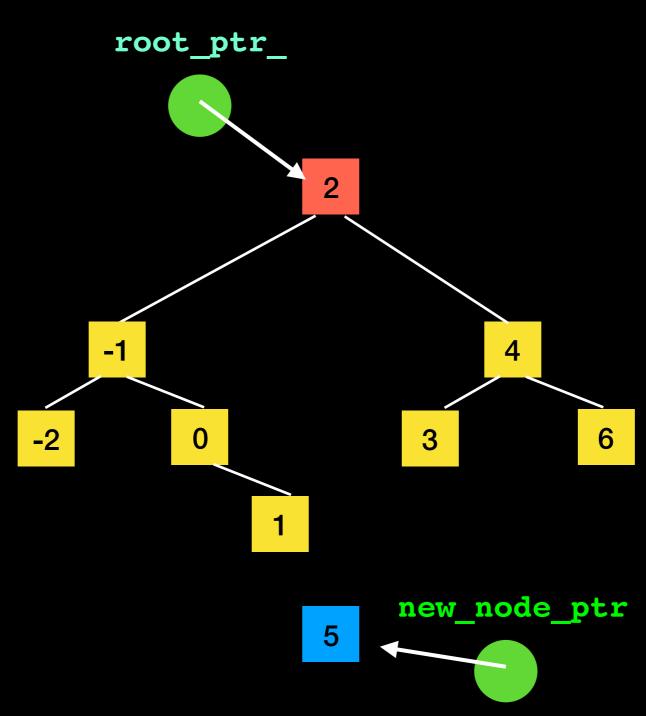

Key methods: determine order of data

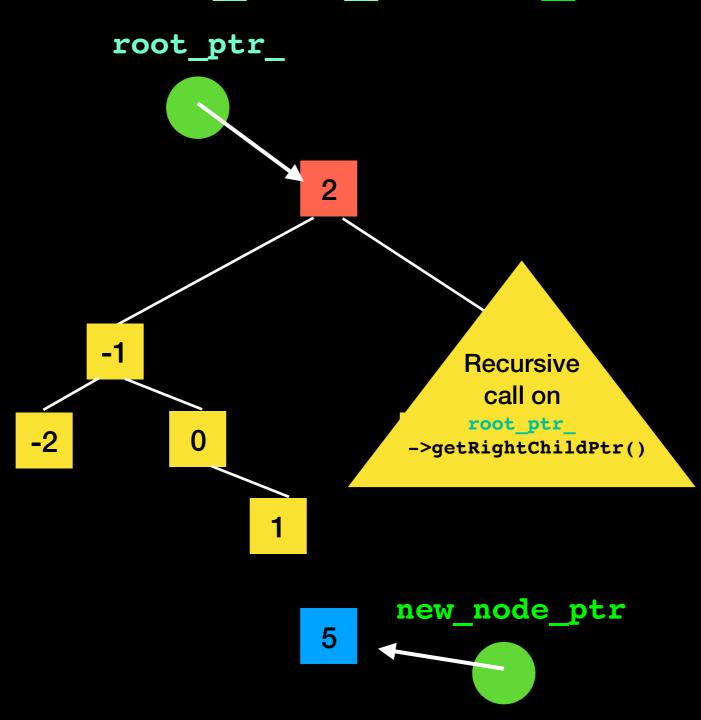

Distinguish between different types of Binary Trees

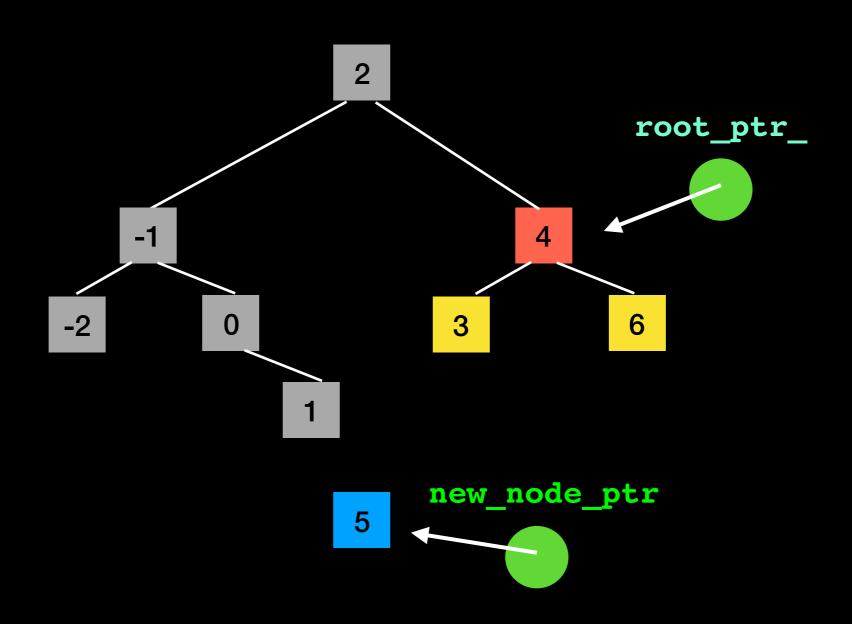

Implement the BST structural property

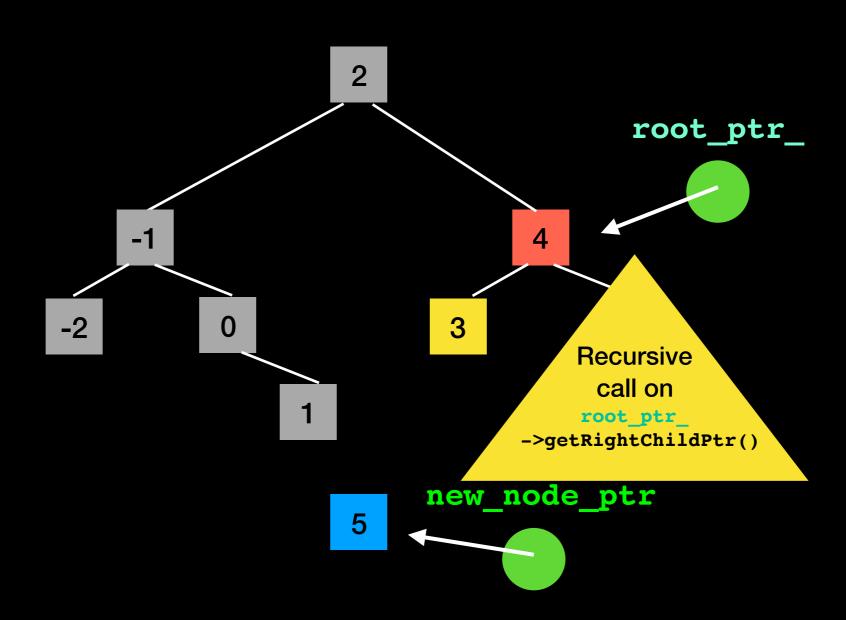

add

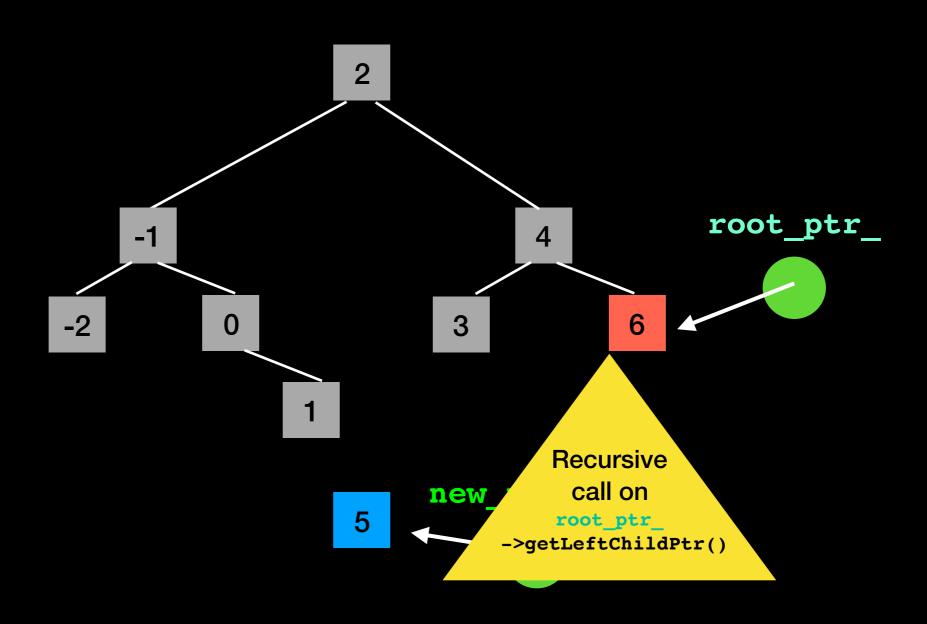

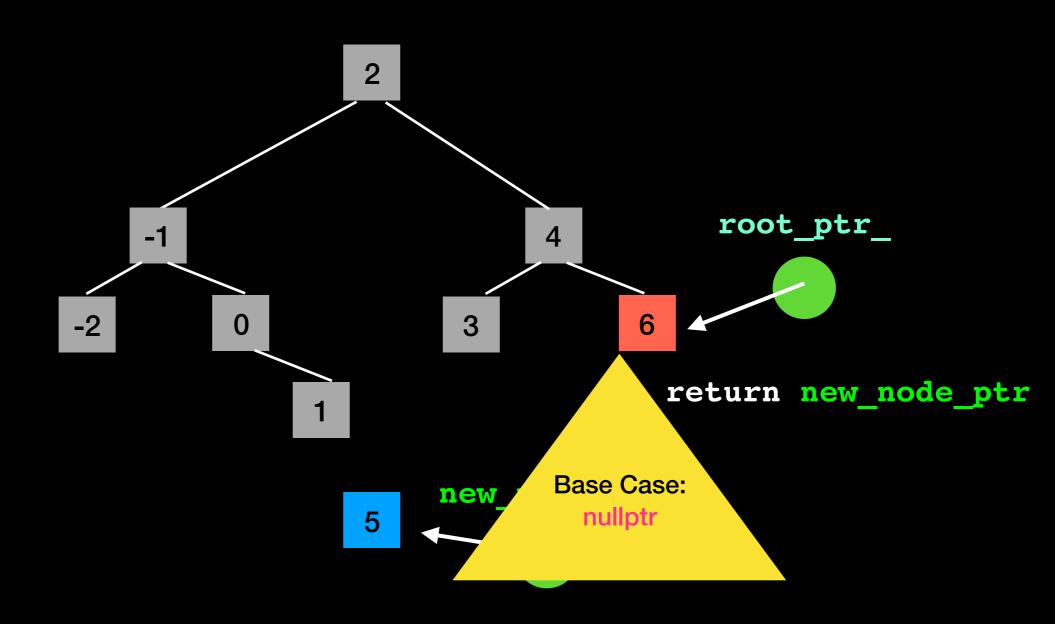

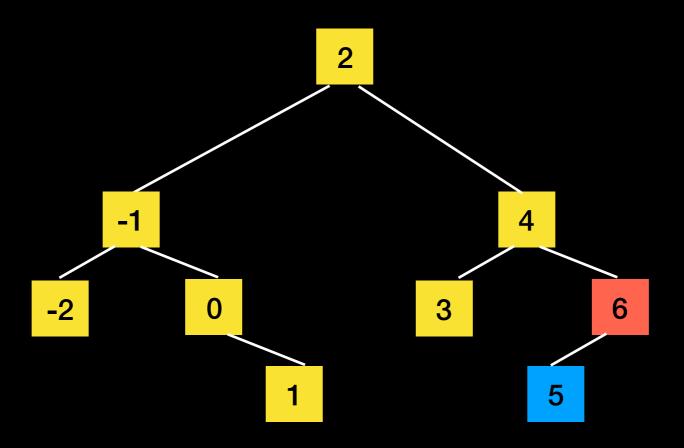

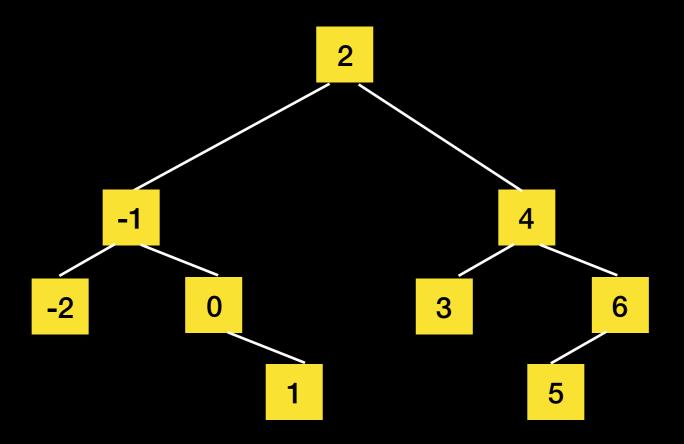

placeNode(root_ptr_, new_node_ptr);

placeNode(root_ptr_, new_node_ptr);

add helper function

```
template<class ItemType>
auto BST<ItemType>::placeNode(std::shared ptr<BinaryNode<ItemType>> subtree ptr,
                              std::shared ptr<BinaryNode<ItemType>> new node ptr)
   if (subtree ptr == nullptr)
      return new node ptr; //base case
  else
      if (subtree ptr->getItem() > new node ptr->getItem())
         subtree ptr->setLeftChildPtr(placeNode(subtree ptr->getLeftChildPtr(),
                                                                  new node ptr));
      else
         subtree ptr->setRightChildPtr(placeNode(subtree ptr->getRightChildPtr(),
                                                                  new node ptr));
      return subtree ptr;
      // end if
   // end placeNode
```

remove

```
template < class ItemType>
bool BST < ItemType >:: remove(const ItemType& target)
{
    bool is_successful = false;
    // call may change is_successful
    root_ptr_ = removeValue(root_ptr_, target, is_successful);
    return is_successful;
} // end remove
```

method does not take pointer parameter.
Only protected/private methods have access to pointers and may modify tree structure

Safe programming: the public

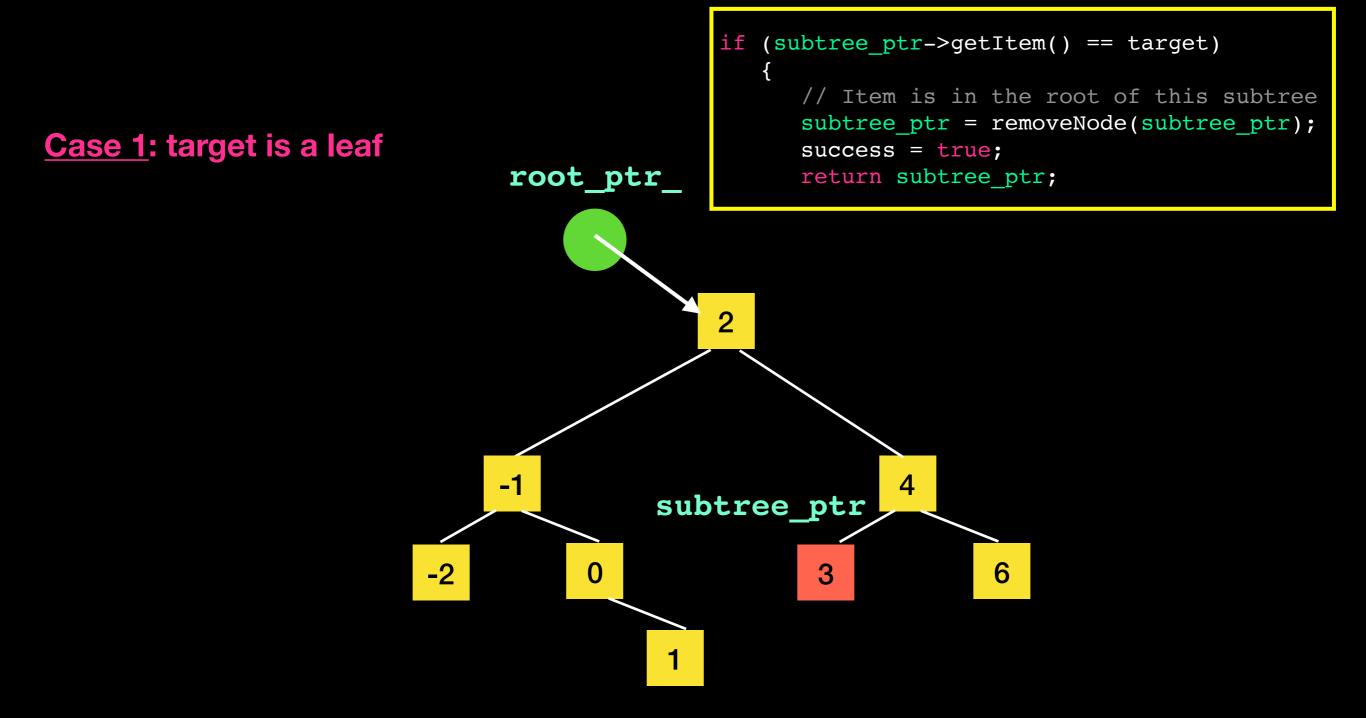

remove helper function

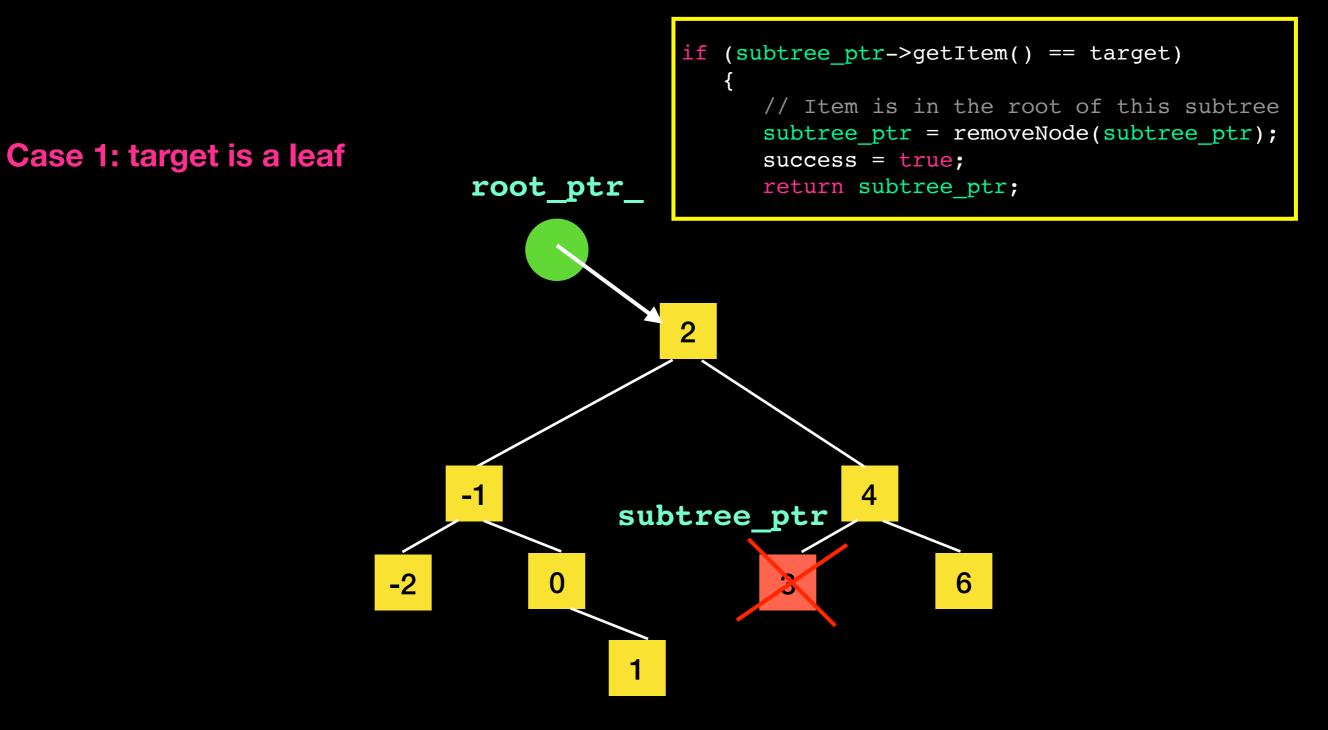

Looks for the value to remove

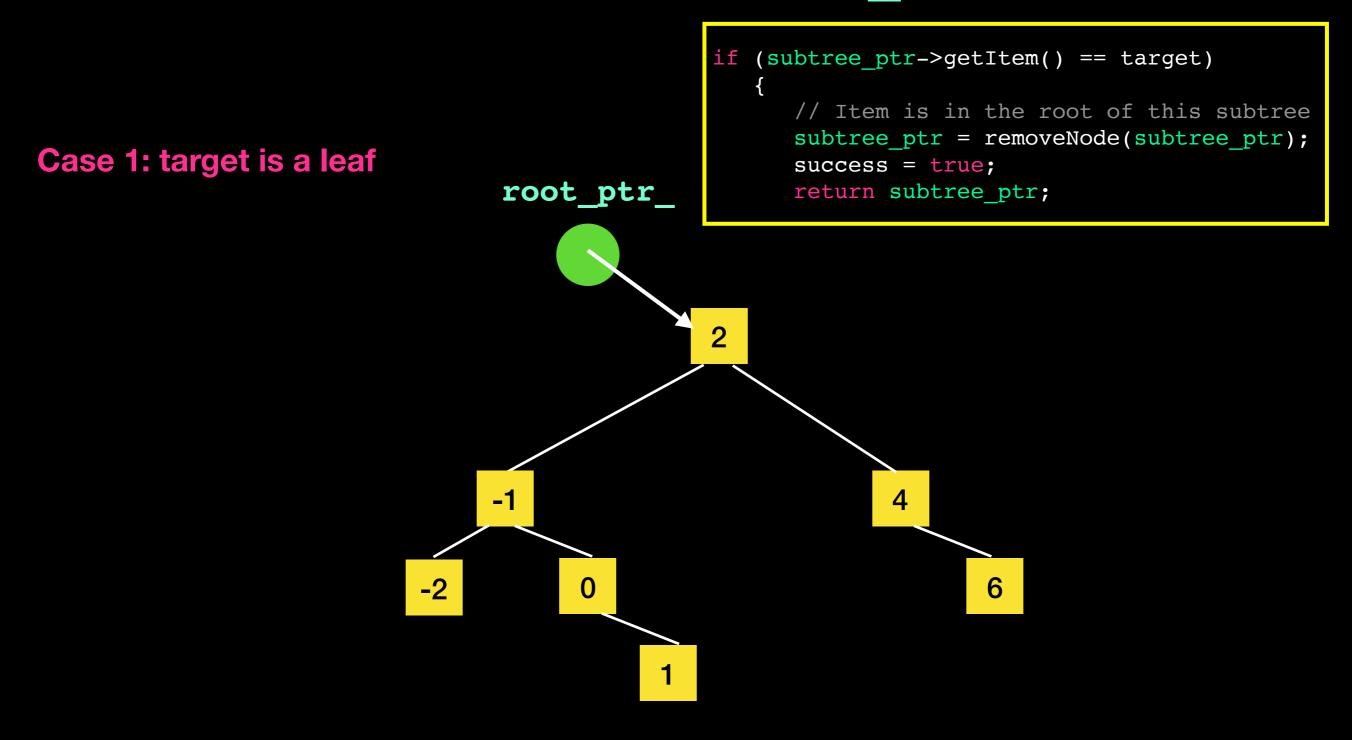

```
template<class ItemType>
auto BST<ItemType>::removeValue(std::shared ptr<BinaryNode<ItemType>>
                       subtree ptr, const ItemType target, bool& success)
   if (subtree ptr == nullptr)
                                                target not in tree
      // Not found here
      success = false;
      return subtree ptr;
                                                            Found target now
      (subtree ptr->getItem() == target)
                                                            remove the node
      // Item is in the root of this subtree
      subtree ptr = removeNode(subtree ptr);
      success = true;
      return subtree ptr;
```

remove helper function cont.ed

```
else
                                                    Search for target in
   if (subtree ptr->getItem() > target)
                                                        left subtree
      // Search the left subtree
      subtree ptr->setLeftChildPtr(removeValue(subtree ptr
                                 ->getLeftChildPtr(), target, success));
                                                      Search for target in
   else
                                                         right subtree
      // Search the right subtree
      subtree ptr->setRightChildPtr(removeValue(subtree ptr
                                 ->getRightChildPtr(), target, success));
   return subtree ptr;
   // end if
   end removeValue
```

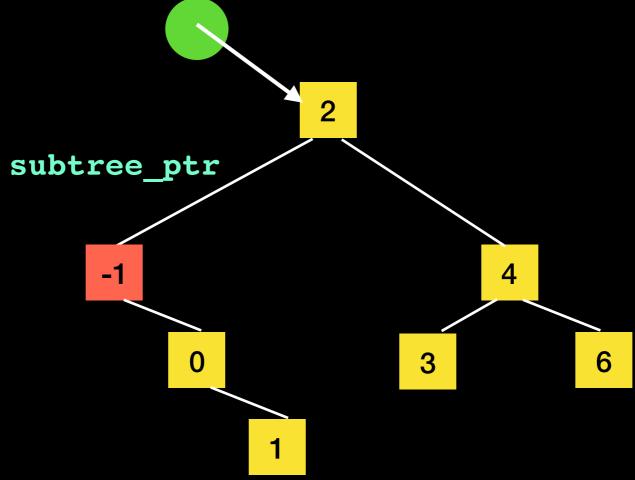

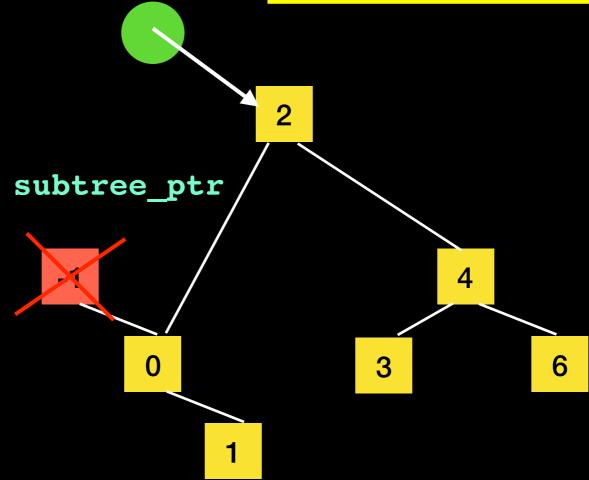

Case 2: target has 1 child Left and right case are symmetric

if (subtree_ptr->getItem() == target)
{
 // Item is in the root of this subtree
 subtree_ptr = removeNode(subtree_ptr);
 success = true;
 return subtree_ptr;

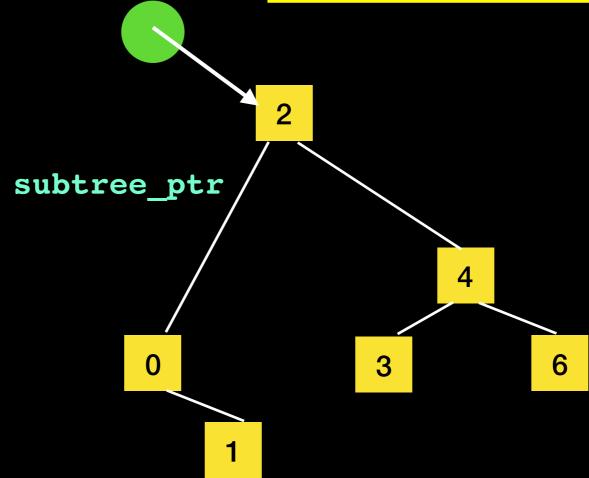

Case 2: target has 1 child Left and right case are symmetric

if (subtree_ptr->getItem() == target)
{
 // Item is in the root of this subtree
 subtree_ptr = removeNode(subtree_ptr);
 success = true;
 return subtree_ptr;

Case 2: target has 1 child Left and right case are symmetric

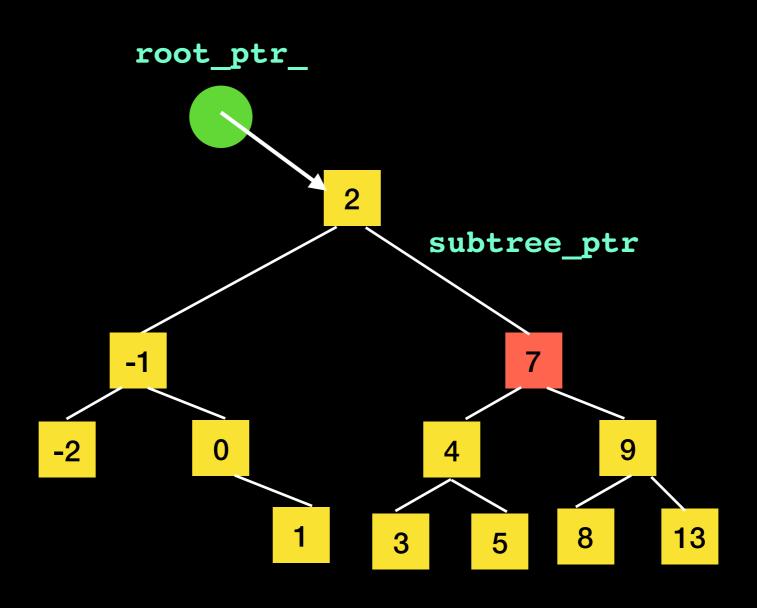

if (subtree_ptr->getItem() == target)
{
 // Item is in the root of this subtree
 subtree_ptr = removeNode(subtree_ptr);
 success = true;
 return subtree_ptr;

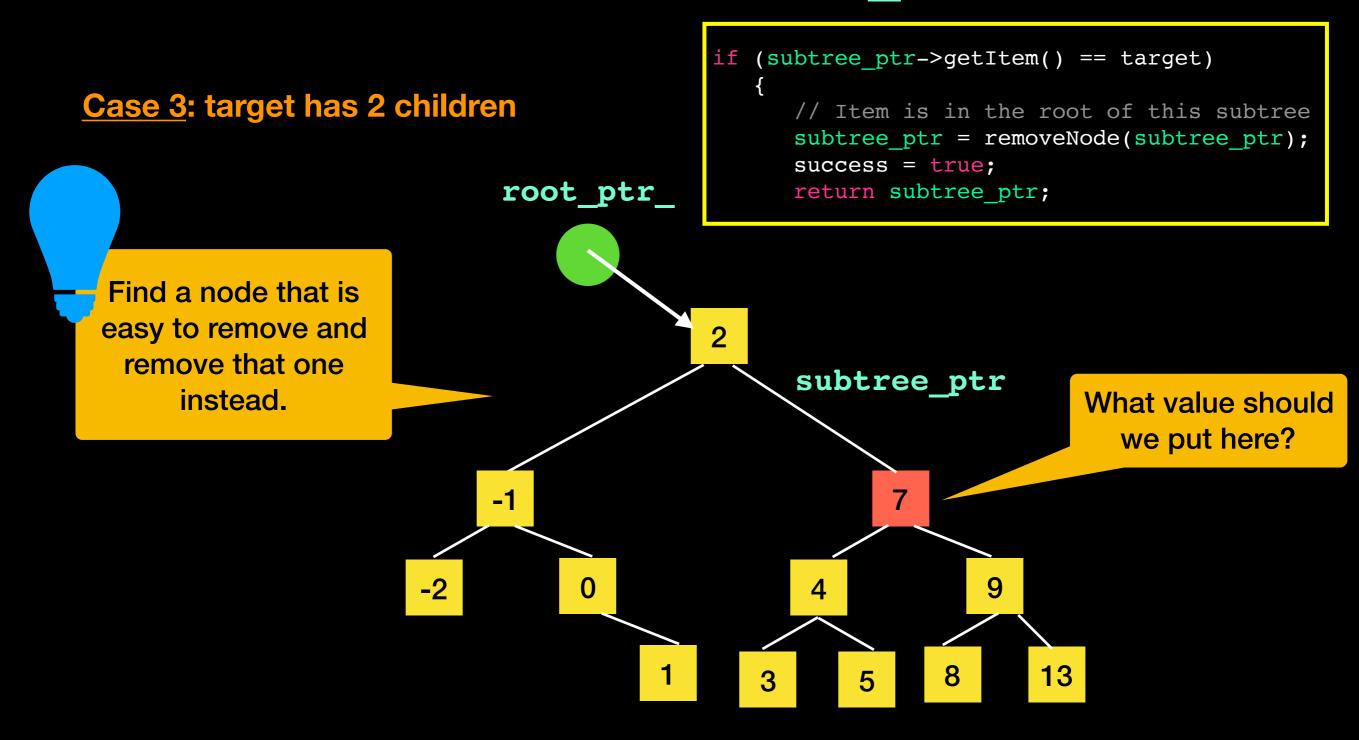

In-Class Task

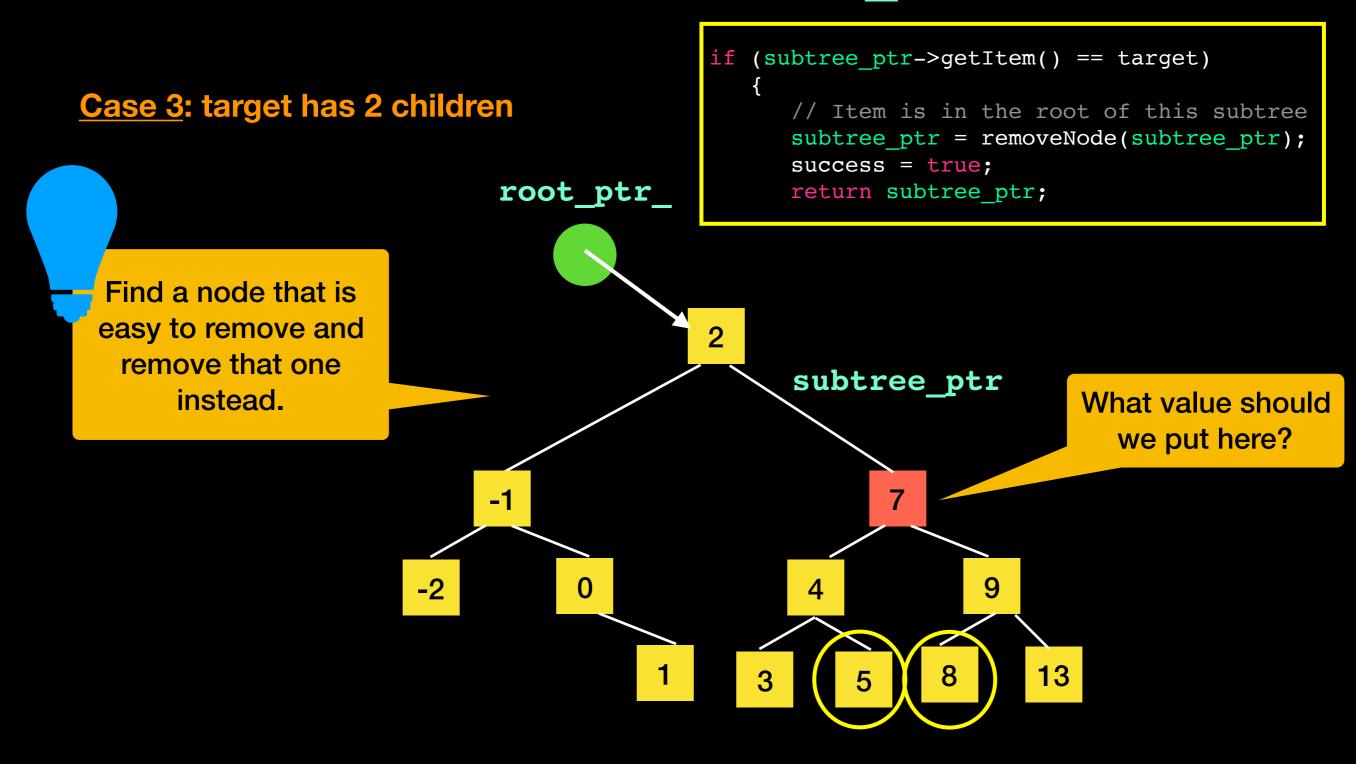

How would you remove node 7?

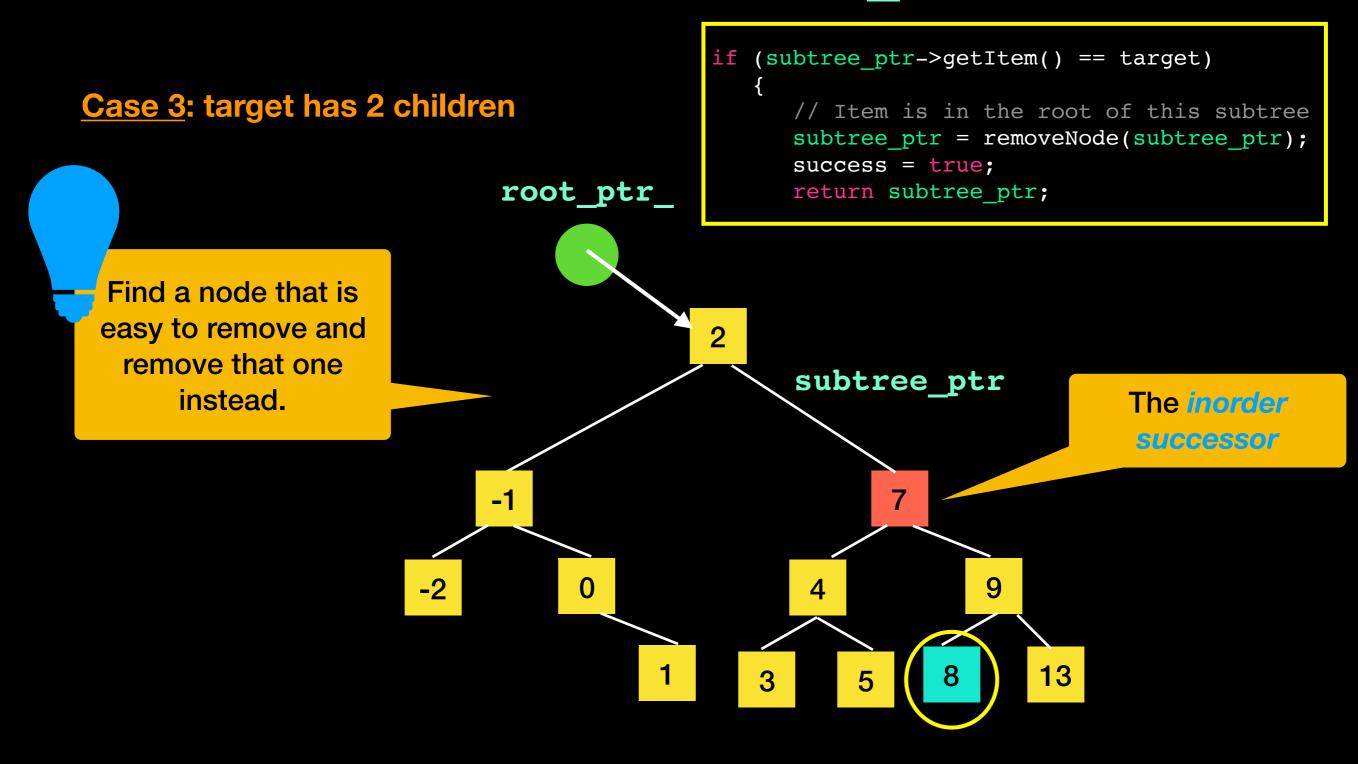

Case 3: target has 2 children

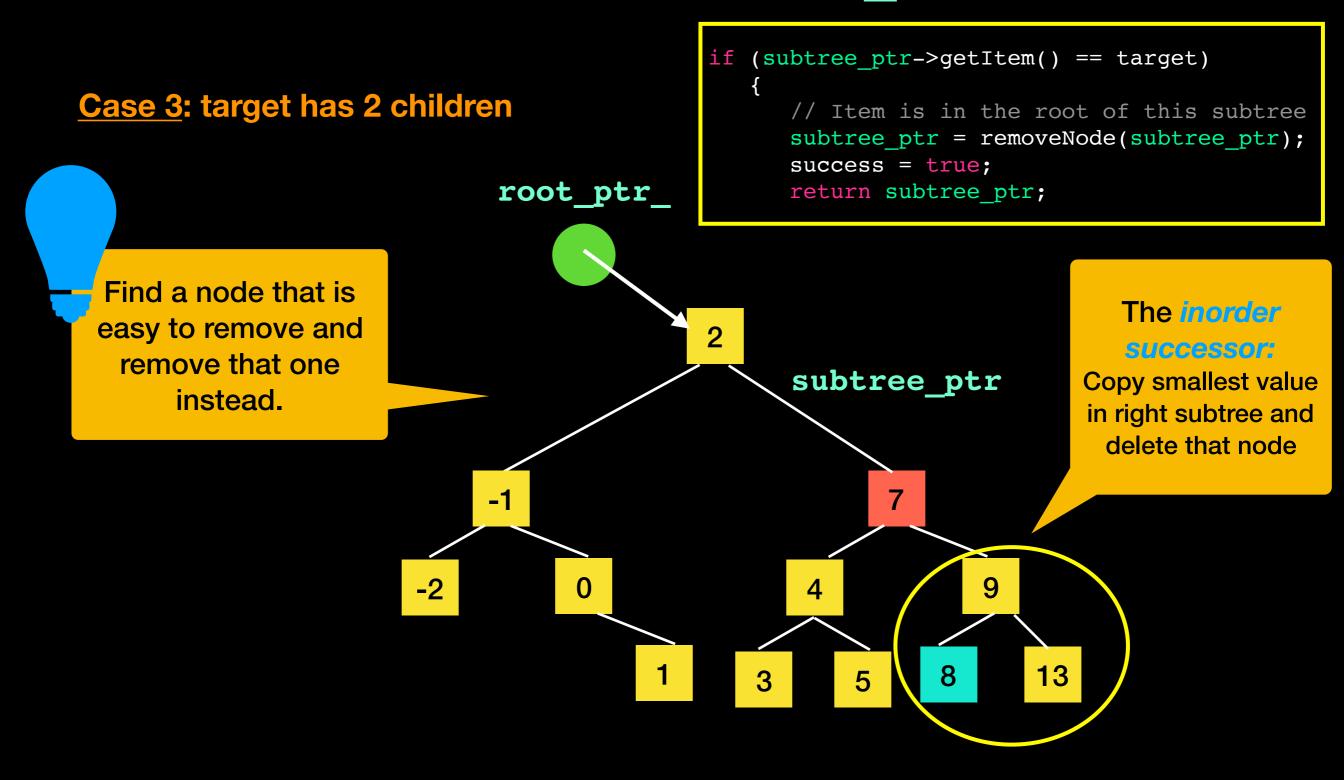

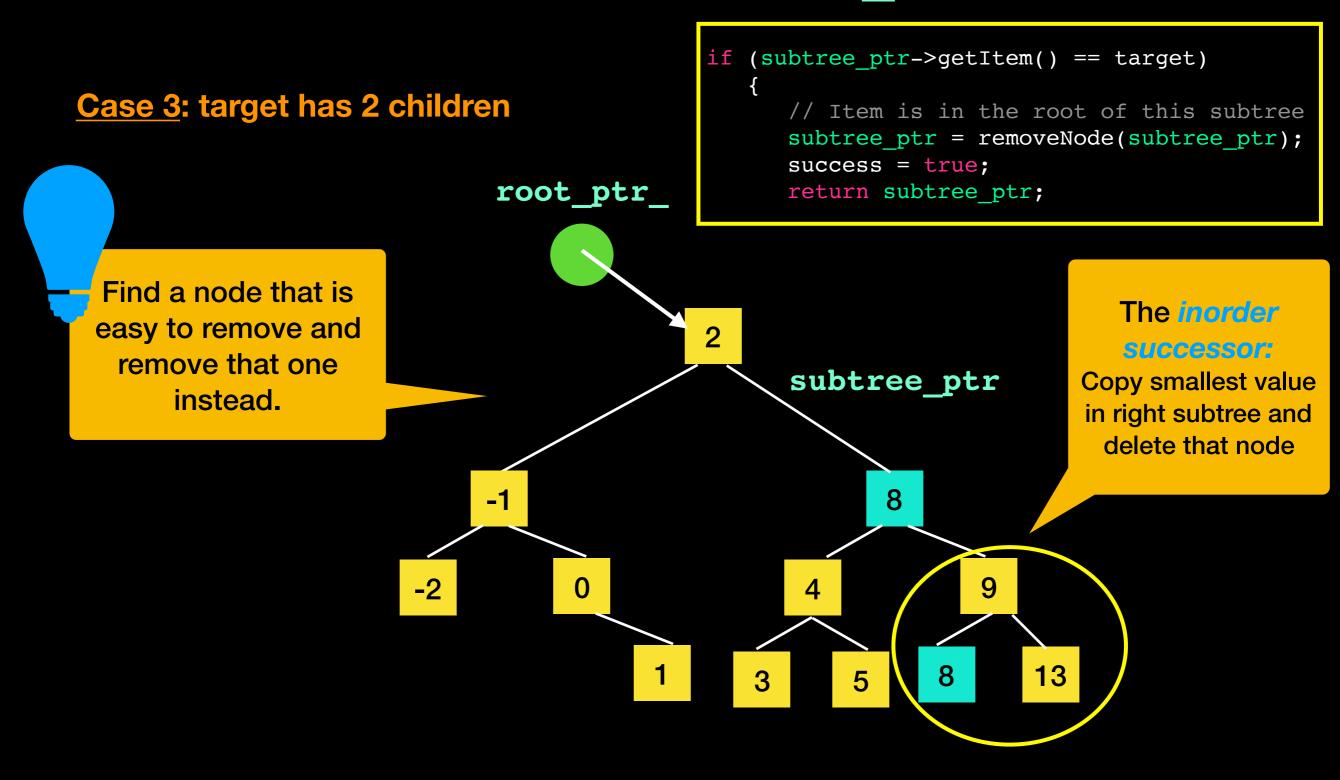

if (subtree_ptr->getItem() == target) Case 3: target has 2 children // Item is in the root of this subtree subtree ptr = removeNode(subtree ptr); success = true; root_ptr_ return subtree ptr; Find a node that is easy to remove and remove that one subtree_ptr instead. 13

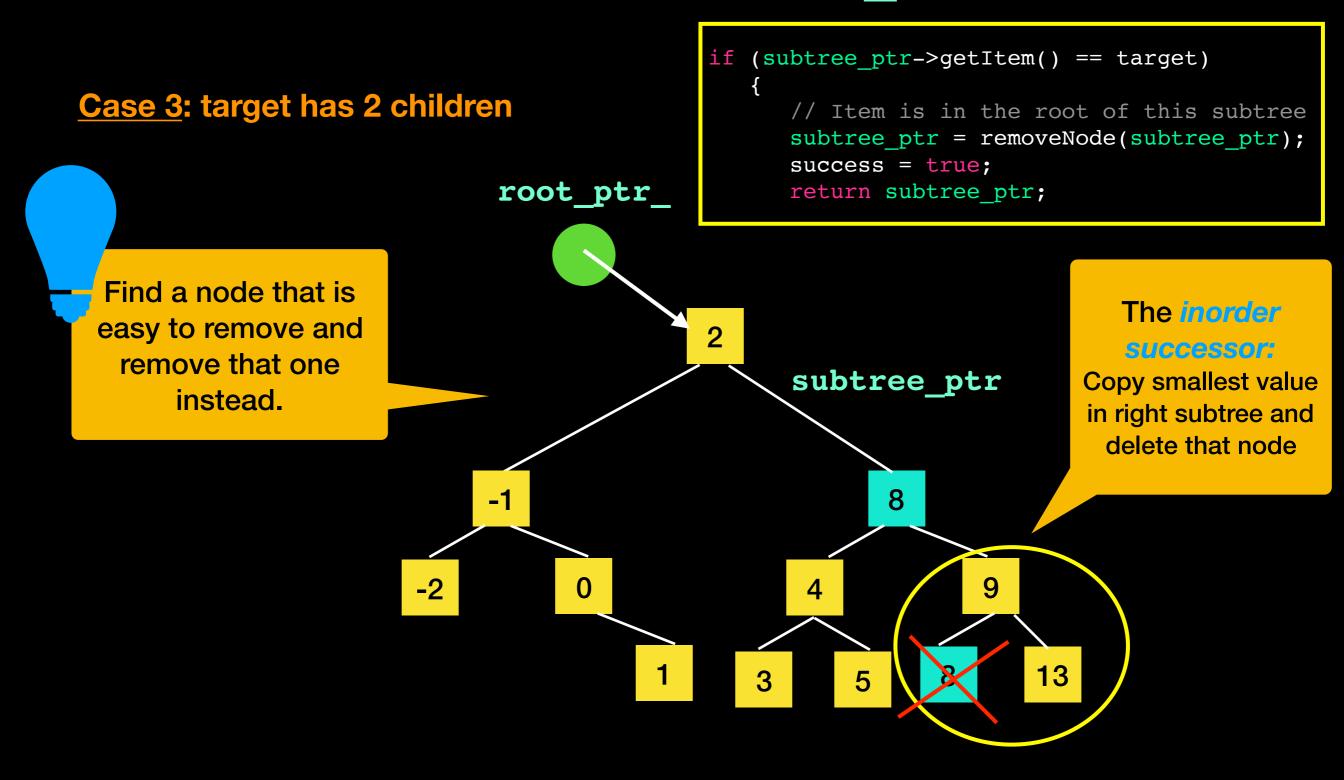

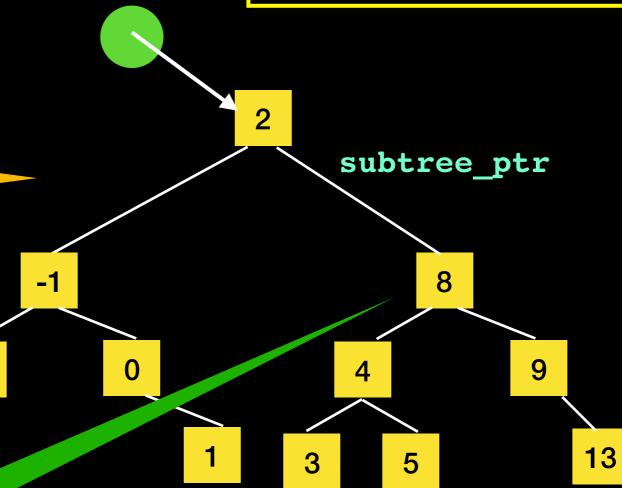

root_ptr_

Case 3: target has 2 children

Find a node that is easy to remove and remove that one instead.

if (subtree_ptr->getItem() == target)
{
 // Item is in the root of this subtree
 subtree_ptr = removeNode(subtree_ptr);
 success = true;
 return subtree_ptr;

This operation will actually "reorganize" the tree

removeNode(node_ptr);

```
template < class ItemType >
auto BST<ItemType>::removeNode(std::shared ptr<BinaryNode<ItemType>> node ptr)
   // Case 1) Node is a leaf - it is deleted
                                                              Node is leaf
   if (node ptr->isLeaf())
      node ptr.reset();
      return node ptr; // delete and return nullptr
                                                                         Node has 1 child
   // Case 2) Node has one child - parent adopts child
   else if (node ptr->getLeftChildPtr() == nullptr) // Has rightChild only
      return node ptr->getRightChildPtr();
   else if (node ptr->getRightChildPtr() == nullptr) // Has left child only
      return node ptr->getLeftChildPtr();
                                                                    Will find leftmost leaf in right
                                                                       subtree, save value in
     Case 3) Node has two children: Node has 2 children
                                                                   new node value and delete
   else
      ItemType new node value;
      node ptr->setRightChildPtr(removeLeftmostNode(node ptr->getRightChildPtr(),
                                                                         new node value));
      node ptr->setItem(new node value);
      return node ptr;
                                                Safe Programming:
                                           reference parameter is local to
      // end if
                                             the private calling function
   // end removeNode
```

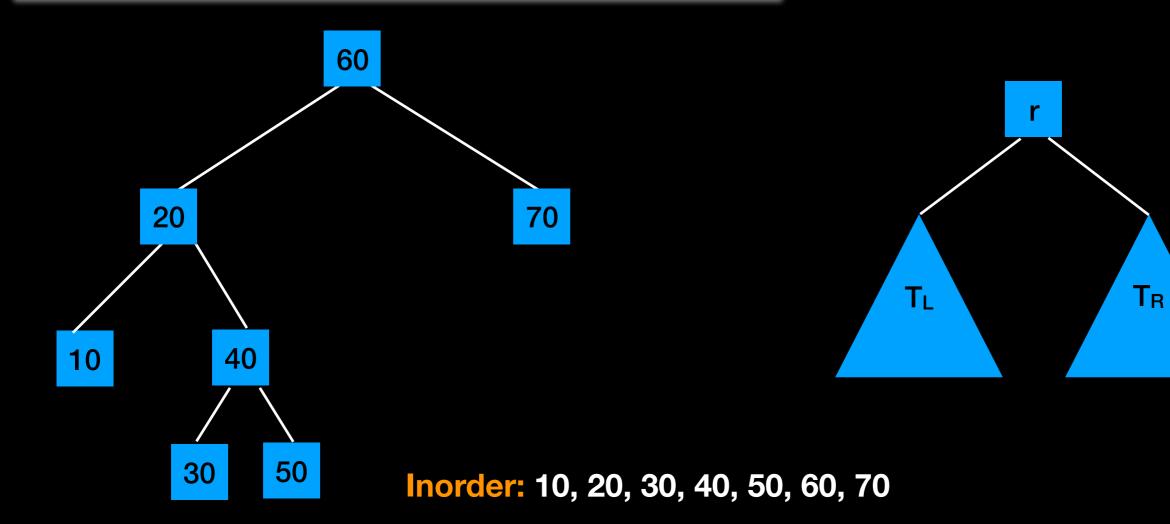

Implement this!!!

```
ItemType find(const ItemType& item) const
{
    //try it at home!!!!
}
```

Traversals

```
template<class ItemType>
void BST<ItemType>::preorderTraverse(void (*visit)(ItemType&)) const
   preorder(visit, root_ptr_);
  // end preorderTraverse
template<class ItemType>
void BST<ItemType>::inorderTraverse(void (*visit)(ItemType&)) const
   inorder(visit, root ptr );
  // end inorderTraverse
template<class ItemType>
void BST<ItemType>::postorderTraverse(void (*visit)(ItemType&)) const
   postorder(visit, root ptr );
  // end postorderTraverse
```

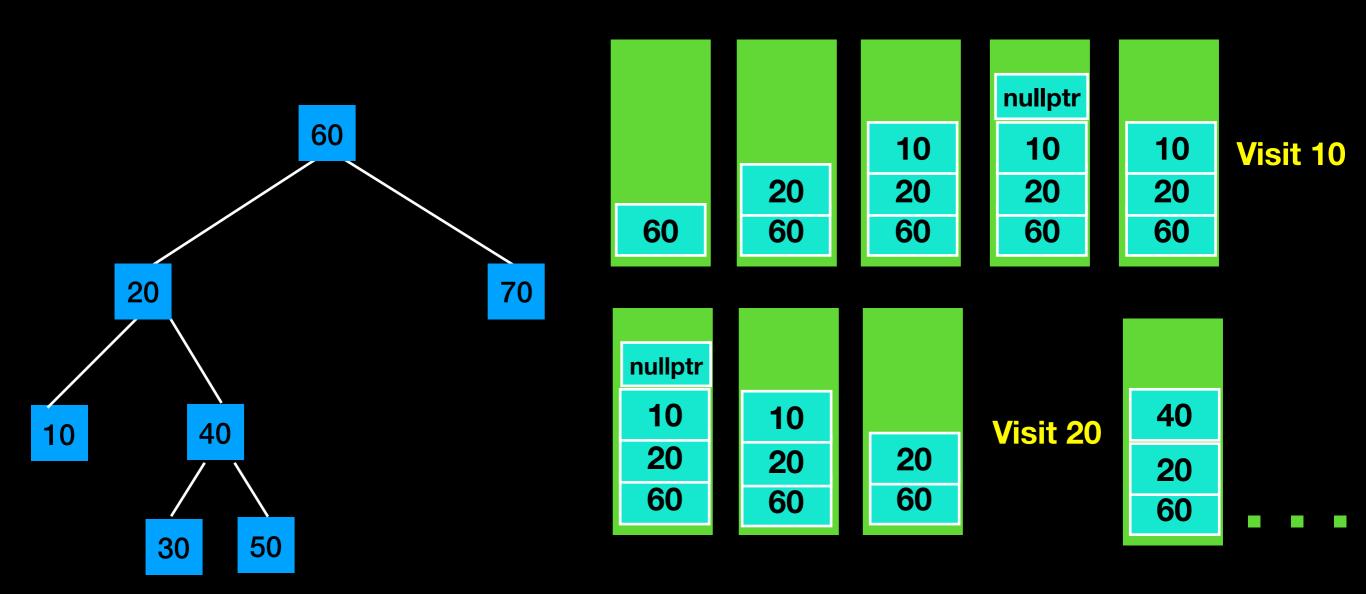

```
\begin{tabular}{ll} \textbf{Visit} (retrieve, print, modify ...) every node in the tree \\ \textbf{Inorder Traversal:} \\ \\ \textbf{if (T is not empty) //implicit base case} \\ \\ & traverse \ T_L \\ & visit \ the \ root \ r \\ & traverse \ T_R \\ \\ \hline \end{tabular}
```

inorderTraverse Helper Function

Recursive Traversal

In recursive solution program stack keeps track of what node must be visited next

Recursive Traversal

With recursion:

- program stack implicitly finds node traversal must visit next
- If traversal backs up to node *d* from right subtree it backs up further to *d's* parent as a consequence of the recursive program execution

Non-recursive Traversal

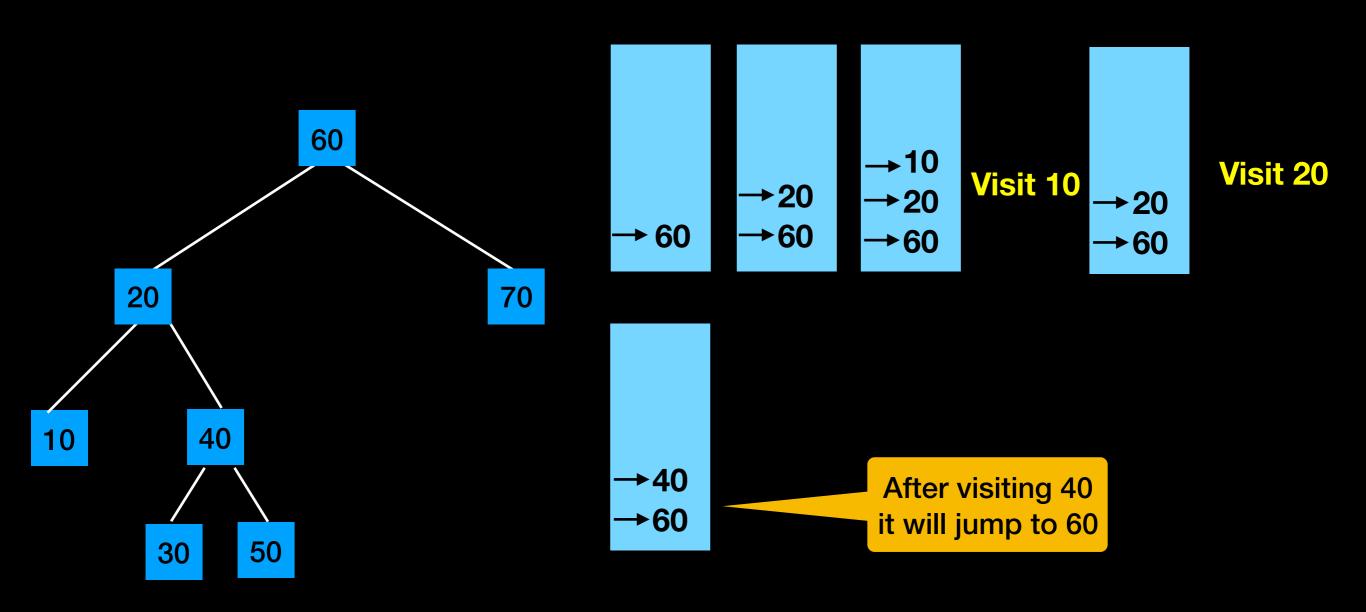

Implement iterative approach that maintains an explicit stack to keep track of nodes that must be visited

Place pointer to node on stack **only** before traversing it's left subtree but **NOT** before traversing right subtree

This will also save some steps that were unnecessary but implicit in recursive implementation

Non-recursive Traversal

Iterative solution explicitly maintains a stack of pointers to nodes to keep track of what node must be visited next

Non-recursive Traversal

```
template<class ItemType>
void BST<ItemType>::inorder(void (*visit)(ItemType&)) const
    std::stack<Itemtype> node stack;
    std::shared ptr<BinaryNode<ItemType>> current_ptr = root ptr ;
    bool done = false;
   while(!done)
        if(current ptr != nullptr)
            node stack.push(current_ptr);
            //traverse left subtree
            current ptr = current ptr->getLeftChildPtr();
```

Non-recursive Traversal cont.

```
//backtrack from empt subtree and visit the node at top of
  //stack, but if stack is empty traversal is completed
  else{
      done = node stack.isEmpty();
       if(!done)
           current_ptr = node stack.top();
           visit(current_ptr->getItem());
           node stack.pop();
           //traverse right subtree of node just visited
           current ptr = current ptr->getRightChildPtr();
end inorder
```

Traversals

We saw this in Project 5

```
template<class ItemType>
void BST<ItemType>::preorderTraverse(void (*visit)(ItemType&)) const
   preorder(visit, root_ptr_);
   // end preorderTraverse
template<class ItemType>
void BST<ItemType>::inorderTraverse(void (*visit)(ItemType&)) const
   inorder(visit, root ptr );
   // end inorderTraverse
template<class ItemType>
void BST<ItemType>::postorderTraverse(void (*visit)(ItemType&)) const
   postorder(visit, root ptr );
   // end postorderTraverse
```

```
void prnt(std::string& x)
    std::cout << x << std::endl;</pre>
int main() {
    std::string a string = "a string";
    std::string anoter_string = "o string";
    BST<std::string> a_tree(a_string);
    a_tree.add(anoter_string);
    a tree.preorderTraverse(&prnt);
    std::cout << std::endl;</pre>
    a tree.postorderTraverse(&prnt);
    return 0;
```

```
root_ptr_

"a string"

"o string"
```

```
a string
o string
a string
Program ended with exit code: 0
```

Traversals

The last cool trick for you this semester

Let's try something different

```
template<class ItemType>
void BST<ItemType>::preorderTraverse(Visitor<ItemType>& v) const
   preorder(v, root ptr );
   // end preorderTraverse
template<class ItemType>
void BST<ItemType>::inorderTraverse(Visitor<ItemType>& v) const
   inorder(v, root_ptr_);
   // end inorderTraverse
template<class ItemType>
void BST<ItemType>::postorderTraverse(Visitor<ItemType>& v) const
   postorder(v, root_ptr_);
   // end postorderTraverse
```

Functors

Objects that by overloading operator() can be "called" like a function

```
#ifndef Visitor_hpp
#define Visitor hpp
#include <string>
template<class ItemType>
class Visitor
public:
    virtual void operator()(ItemType&) = 0;
    virtual void operator()(ItemType&, ItemType&) = 0;
};
#endif /* Visitor_hpp */
```

```
#ifndef Printer hpp
#define Printer hpp
#include "Visitor.hpp"
#include <iostream>
#include <string>
class Printer: public Visitor<std::string>
public:
    void operator()(std::string&) override;
    void operator()(std::string&, std::string&) override;
};
#endif /* Printer hpp */
```

```
#include "Printer.hpp"

void Printer::operator()(std::string& x)
{
    std::cout << x << std::endl;
}

void Printer::operator()(std::string& a, std::string& b)
{
    std::cout << a << b << std::endl;
}</pre>
```

```
#ifndef Inverter hpp
#define Inverter hpp
#include "Visitor.hpp"
#include <iostream>
#include <string>
#include <algorithm>
class Inverter: public Visitor<std::string>
public:
    void operator()(std::string&) override;
    void operator()(std::string&, std::string&) override;
};
#endif /* Inverter hpp */
```

```
#include "Inverter.hpp"
void Inverter::operator()(std::string& x)
    std::reverse(x.begin(), x.end());
    std::cout << x << std::endl;</pre>
void Inverter::operator()(std::string& a, std::string& b)
{
    a.swap(b);
    std::cout << a << b << std::endl;</pre>
```

Traversal with Functor parameter

```
int main() {
    std::string a string = "a string";
    std::string anoter string = "o string";
    BST<std::string> a_tree(a_string);
    a tree.add(anoter string);
    Printer p;
    Inverter i;
    a tree.inorderTraverse(p);
    std::cout << std::endl;</pre>
    a tree.inorderTraverse(i);
    return 0;
```

```
root_ptr_

"a string"

"o string"
```

```
a string
o string
gnirts a
gnirts o
Program ended with exit code: 0
```

Pros and Cons

Beyond the scope of this course, but I'll mention...

Makes a difference when programs become more sophisticated

Mostly has to do with:

- compiler optimization
- functions unable to maintain a state needed for multithreading
- functions require fixed signature while Functors can overload operator() with different parameters
